## Comparison of RTA and SSC Methods for Illex

 2022Presentation to Mid-Atlantic Fishery Management Council
Scientific and Statistical Committee
Hybrid Meeting
Baltimore, MD
Paul Rago
July 25, 2022

## Research Track Assessment Approach

- Overview of multiple lines of evidence
- Approach to bounding feasible estimates of B, F, and Escapement.
- Illustrate potential magnitude of growth, natural mortality and unobserved migrations during fishery.
- Provide framework for inclusion of additional information from fishermen, biologists, oceanographers, and managers
- Suggest areas of research
- Set stage for more complicated in-season depletion models

The Big Picture

## Data Inputs

Landings, Effort and average weight/ individual by Week, 1997-2019

Min spring survey biomasses, 1997-2019.

Models \& Parameters

## Outputs

## SSC Approach

- Data: 1997-2021
- Focus on Escapement Model (exclude Envelope, Leslie Davis, VMS, Mass Balance)
- Use Baranov catch equation instead of Pope's approximation
- Consider full range of uncertainty of parameters rather than just combinations of extreme values
- Updated ranges of parameters based on new research results from RTA
- Consider full range of alternative quota limits
- Compare with candidate BRPs used for other squid stocks
- Escapement
- F/M
- Compute average probability of overfishing over all years given each alternative quota for each candidate BRP
- Relate to Council Risk policy

## Average probability of falling below escapement threshold

- Compute probability of Escapement below threshold for each year.
- Compute average over all years
- This can be done for both the actual OBSERVED catches and the ALTERNATIVE hypothesized catches.

Empirical PDF for Escapement for 2021

Figure 14. Estimated probability of escapement being less than $\mathbf{5 0 \%}$ given alternative catch limits from 24,000 to $60,000 \mathrm{mt}$. Each line is the trajectory of a given year reflecting the effect of different B. 0 by year. The top line is 1999 which had the lowest B.o starting value. The initial population size in each year is based on the observed catch and the range of assumed $\mathrm{q}, \mathrm{v}$, and M values.

Probability Escapement<50\% given Alternative Quota

Estimated probability of escapement less than $\mathbf{5 0 \%}$ given alternative catch limits for each year ranging from 24,000 to 60,000 . Each dot represents an alternative quota with lowest quotas at bottom and highest at top for each year. The initial population size in each year is based on the observed catch and the range of assumed $q, v$, and $M$ values. The solid red line corresponds to the MAFMC's $P^{*}$ risk policy when $B / B m s y>1.5$. The dashed red line is the $P^{*}$ value corresponding to $B / B m s y=0.5$.

Probability Escapement<50\%|Alt Quotas vs Year

Figure 13. Estimated probability of escapement less than $\mathbf{5 0 \%}$ given alternative catch limits for each year ranging from 24,000 to 60,000 . Each dot represents an alternative quota with lowest quotas at bottom and highest at top for each year. The initial population size in each year is based on the observed catch and the range of assumed $q, v$, and $M$ values. The solid red line corresponds to the MAFMC's $P$ *risk policy when $B / B m s y>1.5$. The dashed red line is the $P^{*}$ value corresponding to $B / B m s y=0.5$.

Probability Escapement<50\%|AIt Quotas vs Year

## Potential Changes for 2023

- 2022 Fall Survey data
- Evaluate effects of uncertainty in abundance estimates (4 factors)
- Range of M
- Range of Efficiency
- Range of Availability
- Range of density estimation in each year (Normal, Lognormal)
- Risk analyses unlikely to change much since evaluation is based on many years of data (eg $n$ vs $n+1$ estimates).
- Possible autoregressive model for time series of surveys
- MSE approach? Simple operating model could be developed and used to evaluate escapement risks under different policies.

Questions?

Rest easy--

## Finding F

-1. Expand Fall survey index to total assuming $q$ and $v$

$$
B_{t}=\frac{I_{t}}{q} \frac{A}{a} \frac{1}{v}=\frac{A I_{t}}{q a v}
$$

- 2. Write Bt as function of B.o and $Z \longrightarrow B_{t}=B_{0} e^{-Z t}$
- 3. Baranov catch equation assuming $M$

$$
B_{0}=\frac{C_{t}}{\frac{F}{F+M}\left(1-e^{-(F+M)}\right)}
$$

- 4. Combine Eq. 2 and 3
- 5. Plug Eq. 1 into Eq. 4

$$
B_{t} e^{(F+M)}=\frac{C_{t}}{\frac{F}{F+M}\left(1-e^{-(F+M)}\right)}
$$

-6. Solve for $F$ given assumed levels of $q, v$, $M$ and observations of $I_{t}$ and $C_{t}$ in Eq. 5

$$
\frac{A I_{t}}{q a v} e^{(F+M)}=\frac{C_{t}}{\frac{F}{F+M}\left(1-e^{-(F+M)}\right)}
$$

## Escapement Estimation for OBSERVED Catches

- Find B. 0 and $F$ for each year given $\mathrm{C}(\mathrm{t}), \mathrm{l}(\mathrm{t})$ and assumed $\mathrm{q}, \mathrm{v}, \mathrm{M}$.
- Project terminal population without $\longrightarrow B_{t, \text { without } \text { fishery }}=B_{0} e^{-M t}$ fishery
- Compute escapement as ratio of observed $B(t)$ over $B(t \mid F=0)$
- Or equivalently

$$
\text { Escapement }=\frac{B_{t}}{B_{t, \text { without fishery }}}=\frac{B_{0} e^{-(F+M)}}{B_{0} e^{-M}}=e^{-F}
$$

- This formulation is useful for

$$
\text { Escapement }=\frac{B_{t}}{B_{t, \text { without fishery }}}
$$ evaluating alternative quotas

## Escapement Estimation for ALTERNATIVE Catches

- Find B. 0 and F for each year given observed C(t), I.f(t) and assumed $q, v, M$.
- Assume alternative catch $\mathrm{C}_{\mathrm{H}}$
- Find $\mathrm{F}_{\mathrm{H}}$ associated with alternative catch $\mathrm{C}_{\mathrm{H}}$

$$
B_{0}=\frac{C_{H}}{\frac{F_{H}}{F_{H}+M}\left(1-e^{-\left(F_{H}+M\right)}\right)}
$$

- Compute escapement as ratio of observed $\mathrm{B}(\mathrm{t})$ over $\mathrm{B}(\mathrm{t} \mid \mathrm{F}=0)$

$$
\begin{aligned}
& \text { Escapement }\left(B_{0}, C_{H}\right)=\frac{B_{t}^{\prime}}{B_{t, \text { without fishery }}} \\
& =\frac{B_{0} e^{-\left(F_{H}+M\right)}}{B_{0} e^{-M}}=e^{-F_{H}}
\end{aligned}
$$

## Stochastic methods (1)

- Assume distribution for parameters $q, \mathrm{v}, \mathrm{M}$
- $\mathrm{q} \sim \operatorname{Uniform}\left(\mathrm{q}_{\min }, \mathrm{q}_{\max }\right)$
- $\mathrm{v} \sim \operatorname{Uniform}\left(\mathrm{v}_{\min }, \mathrm{v}_{\text {max }}\right)$
- $\mathrm{M} \sim \operatorname{Uniform}\left(\mathrm{M}_{\min }, \mathrm{M}_{\max }\right)$
- Compute distribution of functions of assumed parameters and observations over the entire range of possible values of $q, v$, and $M$ using equal probability intervals.

## Methods (2)

- Basic approach

- Divide each distribution into N equal probability intervals.
- $\operatorname{Prob}\left(\mathrm{x}_{\mathrm{i}}\right)=1 / \mathrm{N}$ for $\mathrm{x}_{\mathrm{i}}=\mathrm{x} \_\min +\mathrm{i}^{*}((\max -\min ) /(\mathrm{N}-1))$, and $\mathrm{i}=1,2, \ldots, \mathrm{~N}$
- Joint probability obtained by assuming independence of $\mathrm{q}, \mathrm{v}, \mathrm{M}$ such that
- $\operatorname{Prob}\left(q_{i}\right)=1 / N . q$ for $q_{i}=q_{\min }+i^{*}\left(\left(q_{\max }-q_{\text {min }}\right) /(N . q-1)\right)$, and $i=1,2, \ldots, N . q$
- $\operatorname{Prob}\left(\mathrm{v}_{\mathrm{j}}\right)=1 / \mathrm{N} . \mathrm{v}$ for $\mathrm{v}_{\mathrm{j}}=\mathrm{v}_{\text {min }}+\mathrm{j}^{*}\left(\left(\mathrm{v}_{\max }-\mathrm{v}_{\text {min }}\right) /(\mathrm{N} . \mathrm{v}-1)\right)$, and $\mathrm{j}=1,2, \ldots, \mathrm{~N} . \mathrm{v}$
- $\operatorname{Prob}\left(\mathrm{M}_{\mathrm{k}}\right)=1 / \mathrm{N} . q$ for $\mathrm{M}_{\mathrm{k}}=\mathrm{M}_{\text {min }}+\mathrm{k}^{*}\left(\left(\mathrm{M}_{\max }-\mathrm{M}_{\text {min }}\right) /(\mathrm{N} . \mathrm{M}-1)\right)$, and $\mathrm{k}=1,2, \ldots, \mathrm{~N} . \mathrm{M}$
- Assumed N.q=N.v=N.M=40
- Probability for each triple $\left\{\mathrm{q}_{\mathrm{i}}, \mathrm{v}_{\mathrm{j}}, \mathrm{M}_{\mathrm{k}}\right\}$ is $(1 / \mathrm{N} . \mathrm{q}) *(1 / \mathrm{N} . \mathrm{v}) *(1 / \mathrm{N} . \mathrm{M})$
- Sum of probabilities over all N.q*N.v*N.m combinations is equal to one
- Can demonstrate that any function of weighted observations is also a pdf that sums to one. Thus $\mathrm{f}(\mathrm{q}, \mathrm{v}, \mathrm{M} \mid \mathrm{I} . \mathrm{s}, \mathrm{I} . \mathrm{f}, \mathrm{C})$ is a pdf .

## Percentiles and Probabilities of B, F, Escapement

- Compute naïve percentiles from the 64,000 realizations for each year y (N.q*N.v*N.M=403)
- Compare $\operatorname{Esc}\left(\mathrm{y} \mid \mathrm{C}_{\mathrm{H}}\right)$ to some threshold level T, e.g., $50 \%$ escapement
- Compute probability of overfishing (i.e., falling below escapement threshold) as sum of cases over all assumed $\{\mathrm{q}, \mathrm{v}, \mathrm{M}\}$ for all years y where $\left(\operatorname{Esc}\left(\mathrm{y} \mid \mathrm{C}_{\mathrm{H}},\{\mathrm{q}, \mathrm{v}, \mathrm{M}\}\right)<\mathrm{T}\right)$
- Divide this sum by product of number of years times N.q * N.v* N.M
- Composite probability assumes all historical abundance estimates B. 0 (y) are equally likely. This could be refined to account for trend and/or autocorrelation.

## Average probability of falling below escapement threshold

- Compute probability of Escapement below threshold for each year.
- Compute average over all years
- This can be done for both the actual OBSERVED catches and the ALTERNATIVE hypothesized catches.

Empirical PDF for Escapement for 2021

## Parameterization-Bounds for \{q, v,M\}

- Catchability $\mathbf{q}$
- Min=0.078 --expert judgement, \{ key point: >>value used in 2021 (0.01)\}
- Max=0.325 --per analyses of Bigelow-Albatross \& day-night differences
- Availability V per analyses of Manderson et al.'22, Lowman et al.'21
- Min=0.37
- Max=0.73
- Natural Mortality M (per week)
- Min=0.01, per Hendrickson and Hart (lowest assumed value for non spawners)
- $\operatorname{Max}=0.13$, per Hewitt and Hoenig, $\mathrm{A}_{\text {max }}=221$ days per 2019-2020 samples

## Examining the parameter space

Isopleths of Illex biomass (mt) estimates for combinations of $q$ and $v$ for 2021 (left) and marginal distribution of biomass estimates over all combinations of $q, v$, and $M$ (right). Solid red line is median; dashed blue line is mean.

Biomass estimates for fall 2021 s

Empirical PDF for Biomass (mt) for 2021

Isopleths of Illex fishing mortality estimates (per week) for various combinations of $q$ and $v$ for 2021 (top) and derived distribution of fishing mortality rates (per week) for 2021. The dashed black line represents the median value.

Feasible F estimates for fall 2021 survey with Constraints

Empirical PDF for Fishing Mortality (per week) for 2021

Isopleths of escapement as a function of catchability and availability (left) and empirical distribution of Escapement based on observed landings in 2021 and observed NEFSC fall bottom trawl indices (right). The dashed black line=median. Red and blue vertical lines represent escapement levels of 40 and 50\%, respectively

Feasible Escapement estimates for fa

Empirical PDF for Escapement for 2021

Escapement vs estimated fishing mortality/assumed M over all 64,000 combinations of $q, v$, and $M$ for 2021. "Bands" are isopleths for assumed levels $M$. Highest Ms are on the left ( $0.13 / \mathrm{wk}$ ); lowest $\mathrm{Ms}(0.01 / \mathrm{wk})$ on the right.

Escapement vs F/M ratio for 2021

Escapement vs estimated fishing mortality/assumed M over all 64,000 combinations of $\mathrm{q}, \mathrm{v}$, and M for 2019. "Bands" are isopleths for assumed levels M. Highest Ms are on the left ( $0.13 / \mathrm{wk}$ ); lowest $\mathrm{Ms}(0.01 / \mathrm{wk})$ on the right.

Escapement vs F/M ratio for 2021

Percentiles of Biomass, F, and Escapement for each year

## Choosing a Quota Consistent with Council Risk Policy

- Risk of overfishing cannot exceed 0.49 irrespective of relative abundance
- Risk decreases slowly as stock size falls below $1.5 \mathrm{~B} / \mathrm{B}_{\text {msy }}$
- Risk decreases sharply when $\mathrm{B} / \mathrm{B}_{\text {msy }}<1$
- No fishing when
$\mathrm{B} / \mathrm{B}_{\text {msy }}<0.1$

## Candidate Reference Points

- There are no approved Biological Reference Points for Illex
- Percent Escapement levels have been used for other species, e.g.,
- Illex argentinus and Doryteuthis gahi $=40 \%$
- Dosidicus gigas $=40 \%$ (in Mexico, not entire range)

Although L. gahi stocks are nominally managed on an arbitrary target escapement of $40 \%$, the fishery has never been closed early even when escapement has apparently declined below this level.
(Agnew et al. 1998)

- Ommastrephes bartramii=40\%
- The risk of overfishing for Illex can be expressed as the probability of escapement falling below a specific threshold level (say $35 \%, 40 \%, 50 \%$ ) or the probability of exceeding $\mathrm{F} / \mathrm{M}=2 / 3,1$ or other values that attempt to preserve forage for available predators. Finally, one can estimate the joint probability of exceeding F/M threshold and falling below an escapement threshold.
- The only other requirement to apply the risk policy is a guesstimate the likely current state of the resource (i.e., $\mathrm{B}_{\mathrm{t}} / \mathrm{B}_{\mathrm{msy}}$ ).
- Is population trending OR randomly fluctuating about a mean?
- Is that mean about $\mathrm{B}_{\mathrm{MSY}}$ or $0.5 \mathrm{~B}_{\mathrm{MSY}}$ or ??

Figure 13. Estimated probability of escapement less than $\mathbf{5 0 \%}$ given alternative catch limits for each year ranging from 24,000 to 60,000. Each dot represents an alternative quota with lowest quotas at bottom and highest at top for each year. The initial population size in each year is based on the observed catch and the range of assumed $\mathrm{q}, \mathrm{v}$, and M values. The solid red line corresponds to the MAFMC's $P^{*}$ risk policy when $B / B m s y>1.5$. The dashed red line is the $P^{*}$ value corresponding to $B / B m s y=0.5$.

Probability Escapement<50\%|AIt Quotas vs Year

Figure 13. Estimated probability of escapement less than $\mathbf{5 0 \%}$ given alternative catch limits for each year ranging from 24,000 to 60,000 . Each dot represents an alternative quota with lowest quotas at bottom and highest at top for each year. The initial population size in each year is based on the observed catch and the range of assumed $q, v$, and $M$ values. The solid red line corresponds to the MAFMC's $P$ *risk policy when $B / B m s y>1.5$. The dashed red line is the $P^{*}$ value corresponding to $B / B m s y=0.5$.

Probability Escapement<50\%|AIt Quotas vs Year

Estimated probability of escapement less than $\mathbf{5 0 \%}$ given alternative catch limits for each year ranging from 24,000 to 60,000 . Each dot represents an alternative quota with lowest quotas at bottom and highest at top for each year. The initial population size in each year is based on the observed catch and the range of assumed $q, v$, and $M$ values. The solid red line corresponds to the MAFMC's $P^{*}$ risk policy when $B / B m s y>1.5$. The dashed red line is the $P^{*}$ value corresponding to $B / B m s y=0.5$.

Probability Escapement<50\%|Alt Quotas vs Year

Figure 14. Estimated probability of escapement being less than $\mathbf{5 0 \%}$ given alternative catch limits from 24,000 to $60,000 \mathrm{mt}$. Each line is the trajectory of a given year reflecting the effect of different B. 0 by year. The top line is 1999 which had the lowest B.o starting value. The initial population size in each year is based on the observed catch and the range of assumed $\mathrm{q}, \mathrm{v}$, and M values.

Probability Escapement<50\% given Alternative Quota

Figure 15. Estimated probability of escapement less than $40 \%$ given alternative catch limits for each year ranging from 24,000 to 60,000 . Each dot represents an alternative quota with lowest quotas at bottom and highest at top for each year. The initial population size in each year is based on the observed catch and the range of assumed $q, v$, and $M$ values. The solid red line corresponds to the MAFMC's $P^{*}$ risk policy when $B / B m s y>1.5$. The dashed red line is the $P^{*}$ value corresponding to $\mathrm{B} / \mathrm{Bmsy}=0.5$.

Probability Escapement<40\%|AIt Quotas vs Year

And now for some numbers....

Probabilities of falling below various Escapement thresholds for ALTERNATIVE quotas from 24,000 to 60,000 mt. Probabilities represent average over all years 1997-2021.

Probabilities of exceeding various F/M thresholds for ALTERNATIVE quotas from 24,000 to 60,000 mt. Probabilities represent average over all years 1997-2021.

## General Conclusions (1)

- Low q, low v and high M drive the high stock biomasses in Table 2.
- The extreme values, above 1 Mmt seem highly unlikely, but the distribution of median values across years reasonable ( $70-845 \mathrm{k} \mathrm{mt}$ ).
- Wide fluctuations in catch levels occur in other squid fisheries (Falklands)
- Median biomass estimates over the past 10 years have ranged from 112 to 461 k mt (Table 2)
- Median escapement percentiles have exceeded 0.765 for this same period (Table 3).
- Exploitation rates are generally low, $<0.01 /$ week (Fig. 11)
- One has to posit much higher average availability and catchability rates than used herein to significantly reduce median stock size or escapement.
- Escapement estimates herein do NOT consider temporal escapement that occurs outside the fishing season. (or as they say in Scottish salmon fisheries "outwith the fishery")

## General Conclusions (2)

- Probability of falling below a threshold escapement level is computed for (1997-2021, with 2017 and 2020 excluded).
- Average probability depends on all of the realized B.0(y) estimates,1997-2021
- Assumes all initial conditions B.0(y) are equally probable.
- Three low biomass years have been observed: 1999 ( 70 kt , median),2001 (91 kt median) and 2013 (113 kt, median) (Table 2).
- A hypothetical quota of $28,000 \mathrm{mt}$ in 1999 would have resulted a median escapement rate of 50\% (Table 5).
- A hypothetical quota of $43,000 \mathrm{mt}$ in 2001 would have resulted a median escapement rate of $50 \%$ (Table 5).
- A hypothetical quota of $55,000 \mathrm{mt}$ in 2013 would have resulted a median escapement rate of $50 \%$ (Table 5).
- Based on probabilities averaged over all years:
- If $B_{t}$ is stationary and $B / B m s y \sim 1$ and Escapement threshold $=50 \%$ then quotas up to $60,000 \mathrm{mt}$ are possible. (Table 10)
- If $B_{\mathrm{t}}$ is stationary and $\mathrm{B} / \mathrm{Bmsy} \sim 0.5$ then quotas should not exceed $47,000 \mathrm{mt}$ (Table 10 ) or $40,000 \mathrm{mt}$ if $\mathrm{F} / \mathrm{M}=2 / 3$ criterion (Table 11).

## Sources of Uncertainty

- Ranges of parameters for $q, v$, and $M$
- Are they independent?
- Distribution of parameters.
- Uniform is the ultimate heavy tail distribution (other than Beta(0.5,0.5))
- Do we actually know more?
- Knowledge of Illex life history
- Variable growth and maturation rates within and between years
- Importance of cannibalism?
- Year round spawning assumed. Fishery supported by births in Jan and Feb. Importance of other seasons unknown.
- Actual Range of Illex offshore
- Population assumed available within domain of US and Canada surveys.
- Escapement would be higher if population can complete life cycle without migrating on to shelf.
- Candidate reference points
- No analyses of stock recruitment dynamics for Illex illecebrosis or others
- Are \% escapement rates sufficient
- Do empirical or modeling studies support $\mathrm{F} / \mathrm{M}$ thresholds?

Questions?

## Interesting but not essential slides

## Miscellaneous Topics

- How much biomass enters system between the midpoint of the spring survey ( $\sim$ April 1) and the midpoint of the fall Survey ( $\sim$ Oct 1)?
- What does the ratio of Catch over the end of year biomass estimate tell you about potential escapement?
- What if losses due to spawning mortality occur over the entire course of the fishing season?
- How to factor these losses into escapement?

## Mass Balance—How much migration could there be?

- The NEFSC spring bottom trawl survey (BTS) ends before the offshore fishery starts.
- The NEFSC fall BTS begins after most of the fishery has taken place.
- In between a large number of squid are harvested.
- Consider 2019:
- Spring BTS minimum swept area $=1,901 \mathrm{mt}$
- Commercial landings $=28,495 \mathrm{mt}$
- Fall BTS minimum swept area $=3,310 \mathrm{mt}$
- EVEN if no natural mortality, the minimum biomass to support observed landings is $28,495+3,310=31,805 \mathrm{mt}$
- Ratio B. $0 \mid \mathrm{M}=0 / \mathrm{B} . \mathrm{s}=31,805 / 1,901=16.7$

## B. 0 vs B.s disconnect

Figure 9. Distribution of ratio of estimated biomass necessary to support the observed landings in the fishery (B.O) to the initial biomass defined by the spring survey (B.s).

Fishery is supported recruitment in season between time of spring and fall surveys

Empirical PDF for B.0/B.s ratio for 2019

Empirical PDF for B.0/B.s ratio for 2013

## What does Catch over Fall Survey measure?

- Catch over survey biomass is often used as an index of exploitation
- IF survey represents the "average" biomass during the period of exploitation, then $\mathrm{C} / \mathrm{I}$ approximates the Baranov catch equation
- IF survey represents pre fishery abundance and population is closed, then $\mathrm{C} / \mathrm{I}$ approximate exploitation rate (probability of dying due to fishing)
- IF survey represents post fishery abundance, then $\mathrm{C} / \mathrm{I}$ depends on assumed M .
- $C / B_{t}=C /\left(B_{0} e^{-z}\right)$ per Baranov
- $C / B_{t}=C /\left(B_{0} e^{-M}+C e^{-M / 2}\right)$ per Pope's approximation
. Relationship between Escapement and measures of exploitation for 2021. Catch divided by end of year biomass (i.e.. Fall survey) [left] . The trajectories correspond to assumed levels of M. Right panel depicts relationship between escapement and fishing mortality (see Eq. 9).

Escapement vs C/B.f ratio for 2021

## Mathematics for continuous loss of spawners

- Assume that spawners are removed from the population and die soon after.
- Let the rate of maturation be $K$ and the accumulated biomass of spawners be defined as $S_{t} \mid F>0$
- The numerator of escapement ratio can now be defined as the terminal biomass plus the accumulated biomass of spawners when fishing is occurring $\left(S_{t} \mid F>0\right)$
- The denominator is the initial biomass decremented for loss due to natural mortality and maturation plus the accumulated spawning biomass in the absence of fishing mortality ( $S_{t} \mid F=0$ )
- Use modified catch equation to illustrate:
- $\mathrm{Bt}=\mathrm{B} .0 \exp (-(\mathrm{F}+\mathrm{M}+\mathrm{K}))$
- $\mathrm{St} \mid \mathrm{F}>0=\mathrm{K} /(\mathrm{F}+\mathrm{M}+\mathrm{K})(1-\exp (-(\mathrm{F}+\mathrm{M}+\mathrm{K}))) \mathrm{B} .0$
- St|F=0 $=K /(M+K)(1-\exp (-(M+K))) B .0$
