Butterfish 2022 Management Track Assessment

Charles Adams
NEFSC Population Dynamics
charles.adams@noaa.gov

July 25, 2022

Outline

- Methods
- Results
- Biological reference points
- Projections
- ABC/P* projections

NOAA
FISHERIES

Background

- Last benchmark for butterfish was 2021 research track
 - Status: not overfished, overfishing not occurring
- Recommended level of review for June 2022 management track
 - Level 1 (direct delivery)

NOAA
FISHERIES

Methods: model formulation

- WHAM
- Years: 1989–2021
- Ages: 0 to 4+
- $M = 1.278$
- Fishery
 - 1 fleet (landings + discards)
 - 2 selectivity time blocks (1989–2013 & 2014–2021)

NOAA
FISHERIES

Methods: model formulation

- Surveys
 - NEFSC fall Albatross (1989–2008)
 - NEFSC fall Bigelow (2009–2021)
 - NEAMAP fall (2007–2021)
 - NEFSC spring Bigelow (2009–2021)
 - NEAMAP spring (2008–2021)
 - Young-of-the-year index that combines state survey data from ME, MA, RI, CT, NJ and DE (2003–2021)

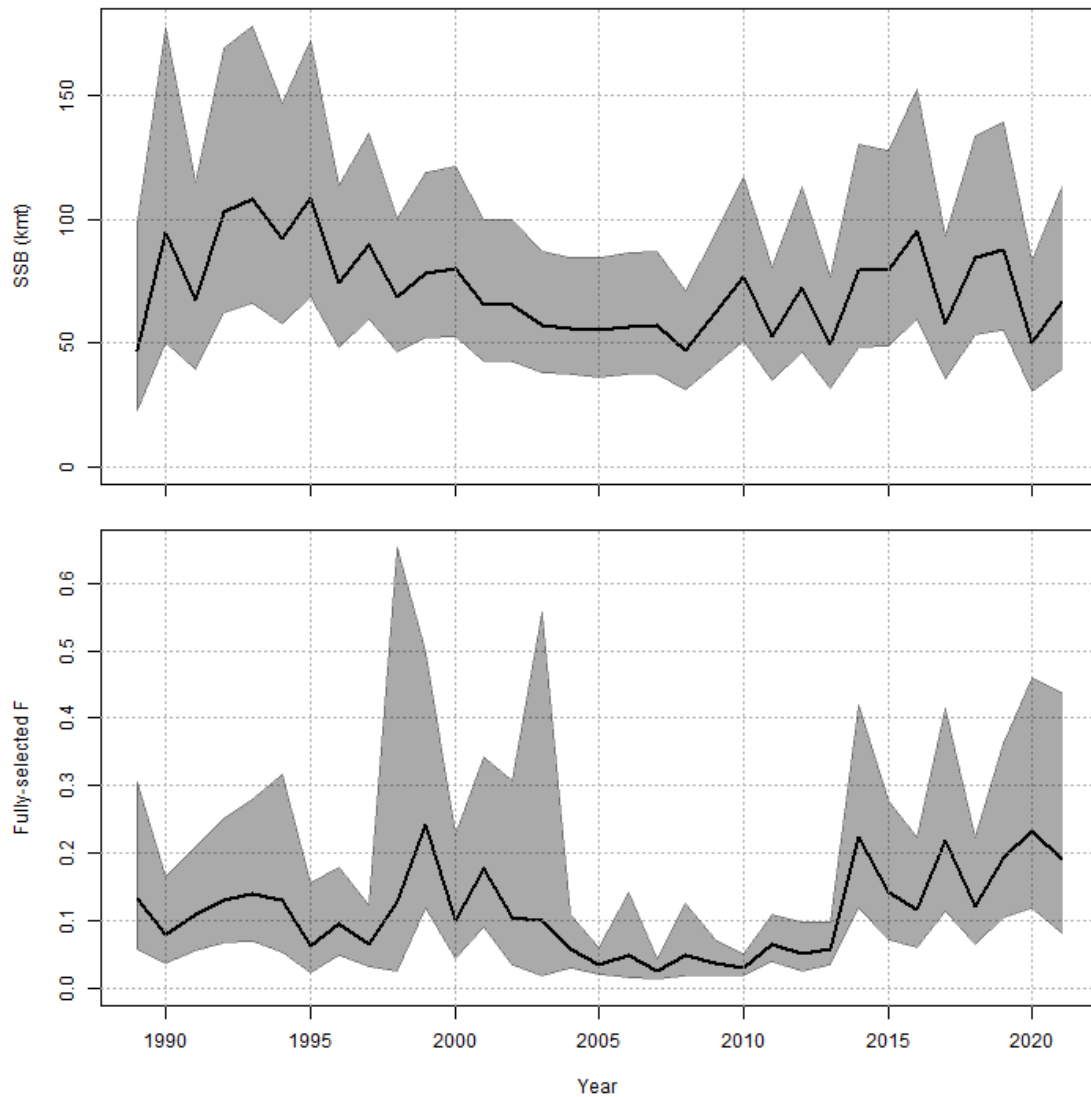

NOAA
FISHERIES

Methods: model formulation

- Estimate all NAA as random effects with AR(1) correlation by year, but independent across ages
- Logistic-normal age composition likelihood
 - Self weighting
 - Allows more general correlation structure than multinomial
 - Has outperformed the multinomial in simulation studies

Historical retrospective

Updated biological reference points

- $F_{50\%SPR}$ and $B_{50\%SPR}$ calculated internally in WHAM assuming
 - Average recruitment over 2011–2021
 - Average SSB per recruit over 2017–2021 (selectivity, maturity, weights at age)
- $F_{50\%} = 5.60$
- $B_{50\%} = 39,436$ mt

NOAA
FISHERIES

Panel concerns about $F_{50\%}$

- The Panel had concerns about the high value (>6 per yr, ~ 99.9% mortality for fully selected ages) for the estimated $F_{50\%}$ reference point
- This latter reference point [i.e., $F = 2/3M$] may be more appropriate given the extremely high value calculated for $F_{50\%}$

NOAA
FISHERIES

New BRPs

- An $F_{40\%}$ proxy was briefly considered, but was abandoned because it was unrealistically high (i.e., ~ 10), and $B_{40\%}$ was less than any biomass in the time series
- An ICES B_{loss} approach was considered but abandoned because the stock does not appear to have ever been depleted

NOAA
FISHERIES

New BRPs

- Assume a symmetrical production curve
 - $B_{MSY} = 0.5 \times B_0$ (in the absence of a stock-recruit curve this equates to $B_{50\%SPR}$)
 - Overfished = $0.5 \times B_{MSY}$
 - Classical theoretical underpinnings
 - Generally in line with the MAFMC's Ecosystem Approach to Fisheries Management guidance for forage fish

NOAA
FISHERIES

Projections

- Assumption that the NAA deviations follow an AR(1) process is continued into the projection period for consistency
- Assumed same recruitment years as reference points
- Assumed same selectivity, maturity, weights at age as reference points
- Assumed maximum annual catch since the resumption of the directed fishery for 2022
 - 5085 mt (2019)

NOAA
FISHERIES

Projections

Year	Catch (mt)		SSB (mt)		F
2022	5,085		76,278	(43,316 - 134,322)	0.263
2023	67,900	(36,451 - 126,481)	45,573	(22,253 - 93,330)	5.596
2024	43,109	(22,001 - 84,468)	39,352	(18,230 - 84,948)	5.596

NOAA
FISHERIES

Uncertainties

- The uncertainty in the reference points (estimation and choice of appropriate BRPs) was not fully considered
- In particular, the uncertainty in the scale of the population was not fully considered because the assumed catchability of NEFSC fall [Albatross] trawl survey heavily affects the $B_{50\%}$ reference point

NOAA
FISHERIES

Summary

- Level 1 (direct delivery)
 - No peer review necessary
- No change in stock status
 - Not overfished, overfishing not occurring

NOAA
FISHERIES

Requested projections for 2023–2024

- Fishing at the current F_{MSY} proxy (5.6) with 150% CV
- Fishing at 2/3M (0.85) with 150% CV
- Fishing at 2/3M (0.85) with 100% CV

- All three assume highest annual catch since resumption of directed fishery for 2022
 - 5085 mt (2019)

NOAA
FISHERIES

Requested projections for 2023–2024

Year	OFL Catch	ABC Catch	ABC F	ABC SSB	ABC P*	
2023	67,900	66,076	5.329	46,479	0.490	F = 5.6 CV = 150%
2024	43,665	39,616	4.838	41,303	0.464	

Year	OFL Catch	ABC Catch	ABC F	ABC SSB	ABC P*	
2023	17,631	17,157	0.824	70,947	0.490	F = 0.85 CV = 150%
2024	16,113	15,681	0.823	65,210	0.490	

Year	OFL Catch	ABC Catch	ABC F	ABC SSB	ABC P*	
2023	17,631	17,267	0.830	70,896	0.490	F = 0.85 CV = 100%
2024	16,096	15,764	0.830	65,138	0.490

SAW 58 F_{MSY} proxy

- Previous F_{MSY} proxy = $2/3M$ based on Patterson (1992)
- Concerns with Patterson (1992)
 - Methods used were intended to identify a reference point that would induce stability in biomass, and not necessarily identify an F_{MSY} proxy
 - Used VPA estimates of biomass and exploitation rate, which are known to produce spurious trends under many circumstances (Lapointe et al. 1989, 1992)
 - Use of stock assessment output as data without due consideration of uncertainty has also been criticized (Brooks and Deroba 2015)
