MEMORANDUM FOR: Sarah Heil,

Assistant Regional Administrator

for Sustainable Fisheries

FROM: David Gouveia,

Assistant Regional Administrator for Analysis and Program Support

SUBJECT: Request for Calculation of Surfclam Size Distribution

Per your request, my staff has reviewed the landings information and biological sampling data for surfclams since the previous size analysis (August 2019 through July 2020), and determined the proportion of surfclams in the fishery smaller than 4.75 inches does not exceed the 30 percent trigger for suspending the minimum size requirement.

Please do not hesitate to contact me with any questions. cc: Potts, Lanning

Estimated Proportion of Undersized Surfclam Landings for 2020

John Sullivan.
Analysis and Program Support Division
Greater Atlantic Regional Fisheries Office
National Marine Fisheries Service
September 14, 2020

Introduction

The Code of Federal Regulations includes a provision for the suspension of minimum landing size regulations for surfclam (*Spisula solidissima*) [CFR 50, §648.75 (b)(3)]:

"upon recommendation of the Mid-Atlantic Fishery Management Council (MAFMC), the Regional Administrator may suspend annually, by publication in the Federal Register, the minimum shell-height standard unless discard, catch, and survey data indicate that 30 percent of the surfclams are smaller than 4.75 inches (12.065 cm) and the overall reduced shell height is not attributable to beds where the growth of individual surfclams has been reduced because of density dependent factors."

Each year an analysis of the size composition of surfclam landings is conducted to inform any recommendation by the Mid-Atlantic Council to the Regional Administrator concerning surfclam minimum size restrictions. The following report summarizes the analysis of Atlantic surfclam landings in 2020.

Data Sources and Procedures

Samples of surfclam landings were collected from the Georges Bank, New Jersey and DelMarVa stock areas. These samples were not evenly distributed and, therefore, had to be weighted by stock area and volume. The coast-wide distribution of undersized surfclams was then calculated.

The estimate for coast wide undersized surfclams landed was determined by calculating a weighted average proportion of undersized surfclams with equation 1:

$$\hat{\boldsymbol{P}}_{c} = \left(\sum_{j=1}^{n} \boldsymbol{W}_{j} \, \hat{\boldsymbol{P}}_{j}\right) \tag{1}$$

where

 $\hat{m{P}}_c$ is the estimated coast wide proportion of undersized surfclams landed

 W_j is the proportion of landings from stock area j in the coast wide reported landings, as calculated with equation 2:

$$W_{j} = \frac{L_{j}}{\sum_{j=1}^{3} L_{j}}$$
 (2)

 L_i is the volume landed (bushels) from stock area j

 $\hat{\boldsymbol{P}}_{j}$ is the estimated proportion of undersized surfclams in stock area j, as calculated with equation 3

$$\hat{\boldsymbol{P}}_{j} = \left(\sum_{i=1}^{n} \boldsymbol{W}_{ij} \, \boldsymbol{P}_{ij}\right) \tag{3}$$

 W_{ij} is the proportion of the landings of sample *i* to total landings of all samples from stock area *j*, as calculated with equation 4:

$$W_{ij} = \frac{l_{ij}}{\sum_{i=1}^{n} l_{ij}}$$

$$(4)$$

 l_{ii} is the volume (bushels) for sample i from stock area j

 p_{ij} is the proportion of undersized surfclams in sample i from stock area j, as calculated with equation 5:

$$p_{ij} = \frac{x_{ij}}{n_{ij}} \tag{5}$$

 n_{ij} is the number of surfclams in sample i from stock area j

 χ_{ij} is the number of surfclams <121 mm in size from sample *i* of stock area *j*

Once the coast wide weighted average proportion of undersized surfclams was determined, the coast wide variance of the proportional mean was calculated and used to determine the 95% confidence intervals around that estimate.

The variance estimate for the proportion of undersized coast wide landings was calculated using equation 6:

$$\operatorname{var}(\hat{\boldsymbol{p}}_{c}) = \sum_{i=1}^{3} \boldsymbol{W}_{j}^{2} \times \operatorname{var}(\hat{\boldsymbol{p}}_{j})$$
 (6)

where

 W_j is the proportion of all landings from stock area j to the coast wide landings from all three areas (Georges Bank, New Jersey and DelMarVa), as calculated with equation 2

 $\operatorname{var}(\hat{\boldsymbol{p}}_{j})$ is the variance associated with each stock area j estimated with equation 7:

$$\operatorname{var}(\hat{\boldsymbol{p}}_{j}) = \sum_{i=1}^{n} W_{ij}^{2} \times \operatorname{var}(\hat{\boldsymbol{p}}_{ij})$$
 (7)

 W_{ij} is the proportion of the landings of sample i to total landings of all samples from stock area j, as calculated with equation 4

 $\operatorname{var}(\hat{\boldsymbol{P}}_{ij})$ is the variance of the proportion of sample *i* in stock area *j* estimated with equation 8:

$$\operatorname{var}(\hat{\boldsymbol{P}}_{ij}) = \frac{\left(\boldsymbol{p}_{ij} \times \left(1 - \boldsymbol{p}_{ij}\right)\right)}{\boldsymbol{n}_{ii}}$$
(8)

The 2020 sampling period extended from August 1, 2019 through July 31, 2020. Surfclam samples were collected from vessels fishing in Georges Bank statistical areas 521, 522, 525, and 562; in New Jersey statistical areas 612, 613, 614, and 615; and in DelMarVa statistical area 622. A total of 161 samples from 23 distinct vessels were used for this analysis of the 2020 sampling period.

Two types of data were used in the analysis: (1) landings information and (2) biological sampling data. Surfclam landings data were collected as part of the Greater Atlantic Regional Fisheries Office mandatory reporting requirements. Vessel and dealer permit holders reported landed volume (bushels), vessel permit number, and fishing location, as well as other information from each vessel trip. This information provided landings data for the principle stock areas. Stakeholder Engagement Division (SED) field staff collected biological samples from selected vessels upon docking. Each sample consisted of shell height measurements from approximately 30 randomly selected individual surfclams. Fishing location of the sampled catch was recorded by SED field staff from information reported by the vessel operators. For length records that lacked area fished information, area fished was determined from the vessel log report for the trip or from the most recent available surfclam log report that included area fished for a particular vessel. Volume of the catch from which the sample was derived was pulled from vessel clam log data for the sampled trip. Oracle tables (sfoqpr and sfoqvr in the sfclam schema on the nero oracle server) were used to query and match vessel trip landings by date and permit

number. If vessel clam log data could not be matched to a sampled trip, dealer-reported volume information for the sampled trip was used. There were several instances where a sampled trip lacked volume landed information from either the vessel clam logs or dealer reports. The volume of these unmatched samples was estimated using the average number of bushels of surfclams landed on all trips by that vessel in fishing year 2020.

Landings information from the principal stock areas indicated that Georges Bank landings made up approximately 37% of the coast wide catch. The remaining 63% of the catch came from the DelMarVa and New Jersey stock areas (Table 1).

Table 1. FY2020 Landings of surfclams reported by vessels August 1, 2019 – July 31, 2020.

| Stock area | Reported Landings (bushels) August, 2019 - July, 2020 | Meat weight of reported landings (lbs.) | Percent of reported landings |
|-----------------|--|--|------------------------------|
| Georges Bank | 599,478 | 10,191,126 | 36.7% |
| New Jersey | 559,000 | 9,503,000 | 34.2% |
| DelMarVa | 476,075 | 8,093,275 | 29.1% |
| Grand Total | 1,634,553 | 27,787,401 | 100.0% |

The nominal length distribution of all biological samples obtained from August 1, 2019 – July 31, 2020 indicated that the majority of surfclams sampled were equal to or larger than 121 mm. The mean length of the coast wide samples was 138 mm (Figure 1).

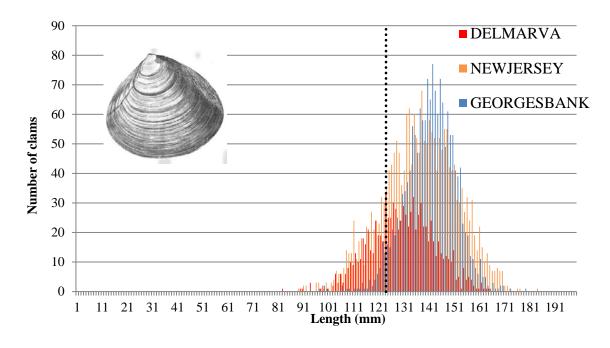

Figure 1. Length frequency distribution of surfclams from dockside sampling for FY2020. The dashed vertical line separates surfclams above and below 121 mm.

The 161 samples used in this analysis contained 4831 measured surfclams, of which 491 individual surfclams were undersized. Fourteen of the 154 samples collected had 30% or more undersized surfclams; 9 of those samples came from the DelMarVa stock area, 5 came from New Jersey, no samples with 30% or more undersized surfclams came from the George's Bank stock area (Table 2).

Table 2. Description of the 161 individual surfclam samples collected in 2020, with the proportion of undersized surfclams in each sample.

| Sample Number | Stock Area | Number of surfclams in sample | Proportion of undersized surfclams* | Volume of catch (bushels) |

^{*}samples with more than 30% undersized surfclams are highlighted.

Estimation Results

An estimated 11.3% of the coast wide surfclam landings to date in 2020 were undersized. The lower and upper 95% confidence bounds for this estimate were 10.7% and 11.9%. These estimates are below the 30% maximum that would preclude the Regional Administrator from suspending the minimum shell height standard (Table 3).

Table 3. Proportional distribution of 2020 undersized surfclams by area and coast-wide.

| Area | Estimated percentage of surfclams <121 mm | Lower 95% Confidence Interval | Upper 95% Confidence Interval |
|--------------|---|----------------------------------|----------------------------------|
| Georges Bank | 1.5% | 1.5% | 1.6% |
| New Jersey | 13.2% | 13.1% | 13.3% |
| DelMarVa | 21.5% | 21.3% | 21.6% |
| Coast-wide* | 11.3% | 10.7% | 11.9% |
